REPORT NUMBER 8. CONTRACT OR GRANT NUMBER(4) AUTHOR(A) Robert R. Dasenbrock PERFORMING ORGANIZATION NAME AND ADDRESS PROGRAM ELEMENT, PROJECT, TASK AREA & WORK UNIT NUMBERS Naval Research Laboratory 54-A-1-20A Washington, D.C. 20375 CONTROLLING OFFICE NAME AND ADDRESS REPORT DATE August 1978 125 15. SECURITY CLASS. (of this report) UNCLASSIFIED Memorandum rept., 15a. DECLASSIFICATION/DOWNGRADING STATEMENT (of this Report) Approved for public release; distribution unlimited. RIBUTION STATEMENT (of the abstract entered in Block 20, If different from Report) 18. SUPPLEMENTARY NOTES 19. KEY WORDS (Continue on reverse side if necessary and identify by block number) Orbit determination Trajectory prediction Least squares Differential corrections Kalman filtering **Orbit prediction** STRACT (Continue on reverse elde if necessary and identify by block number) The orbit determination scheme used for the Navy's SOLRAD HI satellite is discussed in detail. A standard batch and sequential orbit determination method is described. Each program used in the data reduction scheme is discussed and a guide to its operation is presented. Results from the early portion of the mission are included. These include the initial raw ranges and resulting orbits. DD 1 JAN 73 1473 EDITION OF 1 NOV 65 IS OBSOLETE S/N 0102-014-660

#### THE ORBIT DETERMINATION OF SOLRAD 11

#### Introduction

On March 14, 1976 SOLRAD 11 was co-launched with LES-8 and LES-9 into a synchronous orbit with the Titan IIIC. From this parking orbit Solrad 11 was subsequently maneuvered into its final configuration. Basically four different types or orbits were encountered from the time between orbital injection and the final configuration.

#### 1. The Synchronous Arc:

This was basically an eight hour coast between orbital injection and the firing of the PKM. Very little ranging data was received and thus little more than a confirmation of the Standard Orbital Parameter Message (SOPM) was obtained. Tables (1) and (3) indicate the pre-launch nominal synchronous coast orbit and the orbit actually obtained respectively. The close agreement is quite amazing.

#### 2. The Post-PKM Transfer Orbit:

After the PKM was fired and the twenty minute hydrazine burn was completed the spacecraft was allowed to coast for five days. During that time the spacecraft was visible from Blossom Point, MD, for four separate passes. Ample ranging data was received over the period to permit an accurate orbit determination. Considerable trouble was encountered in the ranging system at this time and roughly 50% of the data had to be discarded.

#### 3. Pre-AKM Transfer Orbit:

At the second perigee after PKM a twenty minute hyrazine burn occurred which boasted the apogee height an additional 10,000 km. This was a highly eccentric coasting trajectory and was visible from Blossom Point for a period after the burn and was again visible for a very short period before AKM. The latter pass provided enough additional ranging data to yield a solution of sufficient accuracy to determine the firing time for AKM.

#### 4. Post-AKM Phasing Orbit:

The firing of the AKM circularized the trajectory resulting in a near-zero eccentricity orbit. Short hydrazine burns were given to both the A and B spacecraft over the period of several months in order to separate the spacecraft to their final 180 degree configuration and also raising both their respective semimajor axes to 125,000 km.

#### Description of the Orbit Determination Process

A linear, multistage, stochastic process may be described by [see Ref. 1]

$$x_{i+1} = \phi_i x_i + \Gamma_i w_i$$
  $i = 0, ..., n-1$   
 $p = number of measurements$   
 $n = dimension of state vector$  (1)

where  $x_i$  is a n × 1 matrix denoting the satellite position state vector at stage i,  $\phi_i$  is the state transition matrix which describes the evolution of x from the stage i to i + 1.  $\Gamma_i$  is a known n × r matrix and  $w_i$  is a known r × 1 matrix where r is the number of statistically independent components of the driving noise.

The estimate of the state  $\hat{\boldsymbol{x}}_i$  due to a set of measurements is given by

$$\hat{\mathbf{x}}_{\mathbf{i}} = \overline{\mathbf{x}}_{\mathbf{i}} + \mathbf{K}_{\mathbf{i}} (\mathbf{z}_{\mathbf{i}} - \mathbf{H}_{\mathbf{i}} \ \overline{\mathbf{x}}_{\mathbf{i}}) \tag{2}$$

where  $\overline{x}_i$  is the estimate of the state before the inclusion of the measurements,  $K_i$  is the proportionality matrix or gain,  $z_i$  denotes the actual measurements, and  $H_i$   $\overline{x}_i$  are the predicted measurements based on  $\overline{x}_i$ .

$$K_i = P_i H_i^t R^{-1}$$
 (3)

$$P_{i} = (M_{i}^{-1} + H_{i}^{t} R^{-1} H_{i})^{-1}$$
(4)

$$P_{i} = M_{i} - M_{i} H_{i}^{t} (H_{i} M_{i} H_{i}^{t} + R_{i}) H_{i} M_{i}$$
 (5)

$$M_{i+1} = \phi_i P_i \phi_i^t + \Gamma_i q_i \Gamma_i^t$$
 (6)

H. is the sensitivity matrix and is the sensitivity of the ith measurement with respect to the jth component of the state vector.

M, is the covariance of the error of the estimate before the measurements.  $P_i$  is the covariance of the error after the measurement.  $R_i$  is the measurement weighting matrix. Eq. (5) represents the well known matrix inversion identity. If p < n Eq. (5) is advantageous as the dimension of the matrix quantity (H, M, H, + R, ) is  $p \times p$ . If the measurements are processed one at a time the quantity is a scalar since p=1. On the other hand if  $p \ge n$  Eq. (4) is used as  $(M_i^{-1} + H_i^t \ R^{-1} H_i)$  is always of dimension  $n \times n$ . The components of the process noise are denoted by  $q_i$ .

The state transition matrix  $\Phi$  takes on the following simple form in the (n,  $\xi$ ,  $\eta$ , i,  $\Omega$ , U) coordinate system.

$$\phi_{\mathbf{i}} = \begin{vmatrix}
1 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 1 & 0 \\
(\mathbf{t_{i}} - \mathbf{t_{i-1}}) & 0 & 0 & 0 & 0 & 1
\end{vmatrix}$$
(7)

where

$$x = \begin{pmatrix} n \\ \xi \\ \eta \\ i \\ \Omega \\ U \end{pmatrix} = \begin{pmatrix} (\mu/a^3)^{\frac{1}{2}} \\ e \cos \omega \\ e \sin \omega \\ i \\ \Omega \\ M+\omega \end{pmatrix}$$
(8)

In general either one or an arbitrary number of observations may be processed at a time. In the case of Solrad 11 the range data was assembled from a single ground station. To process a small span of data it was necessary to include the a-priori weighting matrix  $M^{-1}$  in Eq. (4) as the tracking covariance matrix  $(H^{t} R^{-1} H)^{-1}$  was often ill conditioned and thus non-invertable using only a single pass of data. If at least three passes (3/4 revolution) of range data are available, a fair solution may be obtained without weighting the previous solution.

In other words set 
$$M^{-1} = 0$$
 and Eq. (4) becomes
$$P_{i} = (H_{i}^{t} R_{i}^{-1} H_{i})^{-1}$$

$$K_{i} = P_{i} H_{i}^{t} R_{i}^{-1}$$

$$(9)$$

$$\hat{x}_i = \overline{x}_i + K_i[z_i - H_i x_i]$$
 (10)

Eqs. (9) and (10) represent the normal equations for a weighted least squares orbit determination scheme.

The user has several choices available to him. If a new pass of data is to be processed he may either: do a batch fit using the new pass and at least three prior passes of range data and not weight the a-priori covariance matrix or: weight the a-priori covariance matrix and process the new observations recursively. If the previous data are unavailable, the latter procedure is the only choice.

The user has full control over: the number of range data points to be processed, the number of orbital parameters to be determined in the solution, and whether or not to include the a-priori in the new estimate of the orbital parameters.

At present the NRL Blossom Point tracking facility provides only range magnitude data for the SOLRAD HI satellite. The orbit determination program accepts only this type of data. It may easily be modified to accept angle measurements should a future need arise.

The program is highly modular in design. This is advantageous as new algorithms become available they can easily replace their obsolete counterparts. Many of the Fortran subroutines that were used in the orbit prediction module were taken from TRIP (reference 3). The routines that make up the entire program are constantly being updated to improve their efficiency.

#### Orbital Perturbations

The numerical orbit prediction module was designed to be as accurate and fast as possible yet minimizing the required program length since it was to operate within the limited space of the NRL PDP-10. The force field was modeled to include the leading zonal harmonics  $J_2$ ,  $J_3$ ,  $J_4$  and the lunar and solar effects. An analytical ephemeris was provided to give the lunar and solar position as a function of time. Solar radiation pressure was also included. The physical constants used in the program are as follows:

Earth gravitational constant	$398601.5 \text{ km}^3/\text{sec}^2$
Earth radius	6378.135 km
$J_2$	$1.08265 \times 10^{-3}$
$J_3$	$-2.5450 \times 10^{-6}$
$J_4$	-1.6715 × 10 <sup>-6</sup>
Lunar gravitational constant	4902.7 km
Solar gravitational constant	1.3271545 × 1 //sec <sup>2</sup>
Solar radiation pressure at 1 A.U. assuming no reflectivity	$4.7 \times 10^{-6} \frac{\text{newtons}}{\text{meter}^2}$ 2.25 meters <sup>2</sup>
Satellite area	2.25 meters <sup>2</sup>
Satellite reflectivity	0.6
Ellipticity of earth	0.0818188108
Coordinates of tracking antennae at Blossom Point, Maryland:	
Geodetic latitude longitude altitude	38.4314 deg. 282.9135 deg. -0.0247 km.

The orbital elements are referenced with respect to the mean equator-of-date coordinate system. An analytical ephemeris is used to provide the lunar and solar position as required by the numerical integration program. The solar positions are accurate to seconds of arc whereas the lunar positions can be in error up to a degree. While this is acceptable for the numerical integration program it can lead to poor results in the computation of the times of satellite passage through the lunar shadow. An accurate lunar model would require an ephemeris tape. While the use of the entire JPL ephemeris tape is beyond the capability of the NRL PDP-10, the use of an abridged version is presently being investigated.

Although atmospheric retardation effects are not important in the SOLRAD-HI mission, the program does incorporate an atmospheric model. This is described in reference (2).

#### PROGRAM LOAD

This program provides a convenient way to enter a state vector on the keyboard and form an ASCII file which may be used as input to either the orbit determination program or the ephemeris generation program. The operation of this routine is nearly self explanatory. The program may be executed on the NRL PDP-10 by entering the command "RUN LOAD". The first message to appear is:

ENTER THE NAME OF THE ASCII OUTPUT FILE. THIS CAN BE THE INPUT FILE TO EITHER THE ORBIT DETERMINATION PROGRAM OR EPHEMERIS GENERATION PROGRAM: FORMAT (XXXXXX.EXT)

The user must name the output file at this point. This will later become either the input file to the orbit determination or ephemeris generation program. The file contains the initial weighting covariance matrix which may be required by the orbit determination program.

#### ENTER SATELLITE IDENTIFICATION - (A5)

Here the user will enter a five character satellite identification code on the keyboard in format (A5), i.e., enter "SRIIA".

#### ENTER MODIFIED JULIAN DATE - (15)

The five digit integer modified Julian Date of epoch will be entered at this point, i.e., 42787.

#### ENTER HOURS, MIN, AND SEC AS HHMMSS.SSS

Enter the time of day corresponding to the modified Julian Date entered above. Be sure to include leading zeros, i.e., 081305.321.

### RECTANGULAR OR KEPLERIAN INPUT? Type "R" or "K"

The state vector may be entered as a Cartesian or Keplerian state vector.

## FEET OR KILOMETERS Type "F" or "K"

The Cartesian state vector may be entered in terms of feet or kilometers.

#### ENTER X IN KILOMETERS - (FEET) - F20.10)

Enter the X component of the satellite's position with respect to the mean equator of epoch.

#### ENTER Y

#### ENTER Z

#### ENTER XD IN KILOMETERS/SEC (FEET/SEC)

Enter the inertial X component of the satellite's velocity.

ENTER YD

ENTER ZD

#### PERTURBATION PARAMETERS ARE 100011

#### ANY CHANGES?

The six perturbation parameters are  $J_2$ ,  $J_3$ ,  $J_4$ , drag, solar, and lunar forces respectively. "1" means included - "0" means excluded. 100011 means that the effects due to  $J_2$ , the sun and moon are included. If more or less perturbations are to be included enter "Y" for this query in which case the following six additional queries will appear.

#### INCLUDE J2?

If the leading zonal harmonic J2 is to be included in the orbit prediction process type "Y".

INCLUDE J3?

INCLUDE J4?

#### INCLUDE DRAG?

If atmospheric drag is to be included type "Y". This is automatically deleted from the perturbation model for all orbits above 7000 km in semi-major axis.

#### INCLUDE SUN?

#### INCLUDE MOON?

Normally the lunar and solar effects will always be included. Therefore enter "Y" for both of the above.

#### NON-FIXED PARAMETERS ARE 1111110

#### ANY CHANGES?

The orbit determination program includes the provision for fitting any one or all of the following components of the state vector, i.e., the mean motion, e cos ( $\omega$ ), e sin ( $\omega$ ), I,  $\Omega$ , M+ $\omega$ , and BIAS. lllllll0 means that all components are determined except the range bias: By entering "Y" to this query fewer or more components may be fitted. Then the

following additional seven queries will appear:

SOLVE FOR SEMI-MAJOR AXIS?

SOLVE FOR e cos  $(\omega)$ ?

SOLVE FOR  $e \sin (\omega)$ ?

SOLVE FOR INCLINATION?

SOLVE FOR NODE?

SOLVE FOR M+ω?

SOLVE FOR RANGE BIAS?

A range bias may be determined if the range data exists for a time span for more than several days. For short data spans type "N" for this query.

#### PROGRAM ENTER

This program is primarily a means of entering range data into the computer. The program may be run (on the PDP-10) by the single command "RUN ENTER". Time and range information are input whereas predicted range and range rate for each observation are output. Azimuth and elevation of the satellite with respect to Blossom Point are also presented. These quantities are computed with respect to the most recent orbital state vector. The program procedure is described below.

ENTER ALL FILE NAMES IN THE ALPHANUMERIC FORM: XXXXXX.EXTWILL THE NEW RANGE OBSERVATIONS BE ADDED TO AN EXISTING FILE OR ENTERED TO A NEW FILE?

TYPE "A" TO ADD TO EXISTING FILE

TYPE "B" TO BEGIN A NEW FILE

The range observations may be either appended to an existing file or entered into a new file by answering "A" or "B" to the query.

ENTER THE NAME OF THE NEW FILE IN WHICH THE RANGE DATA IS TO BE ENTERED

The file name is to be entered at this point.

#### ENTER NAME OF THE FILE CONTAINING THE INPUT STATE VECTOR

The new observations are compared to the most recent state propagated forward numerically to the time of each new observation. Since numerical integration is used to propagate it is important that a recent solution is used.

FOR ALL QUERIES "?"

Type "Y" - Yes
"N" - No
"S" - Stop

#### ENTER YEAR

Enter "1977" or "77" to correspond to the year. This query is only presented once.

#### ENTER DAY OF YEAR

i.e., enter "320".

ENTER TIME IN FORM: HHMMSS.SSS

i.e., enter "070926.214" for 7 hr 9 min 26.214 sec.

The program responds with (for example)

YR/DAY = 77/320 H/M/S = 7/9/26.214

RANGE RATE = 0.20322 km/sec

PREDICTED RANGE = 125124.19

AZIMUTH = 99.0 DEG

EVELATION = 25.2 DEG

The azimuth is measured clockwise from true north.

ENTER OBSERVED RANGE IN KM

i.e., enter the observed range, e.g. "12512..9"

DIFFERENCE = -0.29 KM

O.K. TO STORE?

The observation may be stored at this point or deleted depending on the size of the difference.

#### ANY MORE OBS?

A "Y" to this query will return the program for more data input whereas a "N" or "S" will terminate the procedure.

```

#### PROGRAM GENER

This program generates a satellite position ephemeris using as input either the output file from the program LOAD or the output file from the orbit determination program. This routine may be initiated by entering ".RUN GENER" on the keyboard.

TYPE "A" - ALERT MODE

"B" - ECLIPSE MODE

"C" - EPHEMERIS GENERATION

"D" - TO UPDATE STATE VECTOR ONLY

"E" - TO LIST STATE AT SPECIFIED INTERVALS

#### ENTER ASCII FILE NAME OF INPUT VECTOR

Enter the file name of the input state vector. This will be any name of the user's choosing.

### FOR ALL QUERIES "?" Type Y or N

GENER incorporates five different program modes. The user selects one by typing "A", "B", "C", "D", or "E" to the first query. The specific use of each option is described briefly below. Each provides the capability to save a copy of the state vector at the end point for further updating at a later time.

ALERT MODE:

If option "A" is selected the program will compute the rise and set times for the satellite described by the input state vector. The times listed are accurate to the nearest minute and indicate the time of zero elevation passage.

ECLIPSE MODE:

Option "B" permits the calculation of all eclipses of the satellite by the earth or or moon (if any) within the selected time period. Four times are given for each eclipse, the beginning of penumbra and umbra and the end of umbra and penumbra passage.

EPHEMERIS GENERATION:

The selection of option "C" initiates the calculation of the satellite ephemeris at two minute time intervals over the time period selected. An abbreviated listing is also available which lists the state vector at 1, 15, 29, 31, 45, and 59 minutes past each hour instead of two minute intervals.

UPDATE STATE VECTOR:

Option "D" allows the user to update the orbital elements of a satellite over a time span to a selected stop time. Only the final state is printed. No intermediate states are listed.

LIST STATE VECTOR AT SPECIFIED INTERVALS:

By using option "E" the state vector may be listed on the teletype and/or disk file at specified intervals.

#### ENTER ASCII FILE NAME OF INPUT VECTOR

Enter the 10 character file designation containing the starting state vector and epoch. This must be entered in the form XXXXXX.EXT.

#### ENTER ASCII FILE NAME OF OUTPUT EPHEMERIS

Enter the 10 character file designation of the ephemeris listing. This will normally be a rather lengthy file as it contains the satellite's state vector every two minutes. The disk storage space required for a one day listing will be approximately 95 blocks. 35 blocks are required for an abbreviated listing.

#### INITIAL STATE AND EPOCH FOR "SR11A" ARE

The state vector will be listed at this point.

#### ENTER MOD JULIAN DATE OF START TIME

Enter the five digit integer corresponding to the modified Julian date of the start time (beginning of the ephemeris generation); e.g., 43295 for June 1, 1977.

#### ENTER HOURS & MIN IN FORM HHMM

Enter the hours and minutes of the day. Include leading zeros, e.g., 0905.

#### MOVE STARTING POINT BY X.XXXX DAYS

Normally the starting point of the ephemeris may be several hours ahead or behind the epoch time. This message only confirms this. The program may be terminated at this point if any input error has been made.

#### INITIAL STATE AND EPOCH FOR "SR11A" ARE

The new starting state vector will appear.

#### ENTER MODIFIED JULIAN DATE OF STOP TIME

#### ENTER HOURS & MIN IN FORM HHMM

#### INTEGRATION TIME SPAN = X.XXXX DAYS

This message confirms the integration time span. Remember 95 blocks/day are required to store the ephemeris file. If the integration time span is some large number, e.g. 10000 days, an input error has been made and the program should be terminated.

#### ROUTINE DOES NOT WORK FOR REVERSE TIME SPAN

If by any chance a negative time span is requested the above message will appear and the program will be terminated. This restriction is only applicable to option "C". The numerical integration scheme works in reverse for all other options.

#### FINAL STATE IS

The final state vector will be listed on the terminal.

#### SAVE FINAL STATE VECTOR?

If "Y" is given to the above query then the following:

#### ENTER ASCII FILE NAME OF OUTPUT VECTOR

List the file name of the output state, i.e. "ABIRD.OUT". This file will be catalogued as a permanent file on the disk. It may be subsequently used as input to either ENTER, GENER, or DIFFCR.

Table (3) Sample Output of the Program GENER. Ephemeris option.

#### ORBIT DETERMINATION PROGRAM

The operation of the orbit determination program is designed to be nearly self explantory. The user has control of the range data reduction via an interactive mode. The program may be initiated by entering "RUN DIFFCR" on the terminal.

#### ENTER NAME OF THE FILE CONTAINING THE RANGE MAGNITUDE DATA

Enter the 10 character file designation of the range magnitude data, i.e., "ABIRD.RNG".

#### ENTER NAME OF THE FILE CONTAINING THE INPUT STATE VECTOR

This file will be the a-priori orbital state vector as required by the orbit determination program. It may correspond to the Standard Orbital Parameter Message. The ASCII file referred to here will be generated using the program LOAD.

## ENTER NAME OF THE FILE CONTAINING THE UPDATED OUTPUT STATE VECTOR REFERENCED NEAR THE START OF THE DATA SPAN

The state vector as referenced to the beginning of the data span will be recorded in an ASCII file by this name of the user's choosing, i.e., "ABIRD.STA". This may later become the input file to the ephemeris generation program.

### ENTER NAME OF THE FILE CONTAINING THE UPDATED OUTPUT STATE VECTOR REFERENCED NEAR THE END OF THE DATA SPAN

Enter any name, i.e., "ABIRD.END". The new state vector will be equivalent to "ABIRD.STA" but its epoch will be referenced to a time near the end of the data span. This also may be used as the input file to the ephemeris generation program or the orbit determination program in its sequential mode should a new batch of range data be processed.

## NON-FIXED PARAMETERS ARE 1111010 ANY CHANGES?

The input state vector contains a seven integer key which indicates which of the seven components of the state vector are to be held fixed in the orbit determination process. "l" indicates that it may vary in the orbit fitting scheme. "O" indicates it is to be held fixed. The seven parameters are: mean motion, e cos ( $\omega$ ), e sin ( $\omega$ ), I,  $\Omega$ , M+ $\omega$ , and BIAS. e.g. 1111010 means that the nodal angle and the bias parameter are to be held fixed. If "Y" is given to the above query the following message will appear.

#### ENTER NEW PARAMETERS - 17

i.e., enter "1110010".

#### ENTER STARTING OBSERVATION NUMBER Enter 1 if beginning - I4

Normally one will begin processing the observations at the beginning of the data span in which case the integer "1" should be entered on the keyboard. However should you wish to begin at one of the later points enter the number assigned to that point. The data points are numbered sequentially from one in steps of unity.

#### WEIGHT A-PRIORI ESTIMATE?

If the new observations are to be weighted with the old, type "Y". This will be the case if only a few observations are to be processed, i.e., when in the sequential mode. However the range observations may be used to solely determine the state update if sufficient data exists over a time span of several days or more. In this case type "N". Naturally the a-priori estimate may be weighted with the new observations in either mode of operation.

#### ENTER NUMBER OF RANGE OBSERVATIONS TO BE PROCESSED

All of the observations may be processed at once in which case enter the total number of observations in integer form (or any larger number). However if only a few observations are to be processed, and the a-priori estimate is weighted, then enter the number in integer form. As few as one or all observations may be processed at a time.

#### LIST INDIVIDUAL RESIDUALS?

The observed minus the computed range magnitudes will be listed if "Y" is given to this query.

#### EDIT O-C ARRAY?

The range data points may be edited at this point by entering "Y". If so the following message appears:

### AUTOMATIC OR MANUAL EDITING? Type "A" or "M"

The individual range data points may be deleted automatically or manually.

#### RMS = XXX.XXX

#### ENTER DELETION THRESHOLD - F10.3

Here the user must enter the deletion threshold. For example, if the RMS for a batch of data is 2.5 km and 5.0 is entered, then all range observations having a residual greater than 5.0 km will be deleted. The same bad data points must be deleted at each iteration of the differential corrections procedure.

#### LIST THE STATE VECTOR "ABIRD.STA"?

The new estimate of the state vector at the end of each iteration may be listed on the line printer by typing Y. In either case it will be written on the ASCII file under the name "ABIRD.STA" or any name of the user's choosing. This state vector has an epoch time one minute past the first hour prior to the first range observation being processed. In the batch mode this quantity will normally be listed on the line printer.

#### RETURN FOR ANOTHER ITERATION?

If the differential corrections procedure has converged to a satisfactory solution the iteration procedure may be terminated by typing "N". If "Y" is entered another iteration will be computed. Normally four to five iterations are necessary for convergence to a sufficiently accurate state estimate.

#### COMPUTE TRACKING COVARIANCE MATRIX AGAIN?

If the initial vector is sufficiently accurate this matrix need only be computed once and "N" will be entered on the keyboard. If however each successive iteration produces a state vector sufficiently different from the previous iteration this quantity may be recomputed by entering "Y".

#### UPDATE EPOCH TO TIME NEAR LAST OBSERVATION?

If desired, the epoch may be updated to a time near that of the last observation processed; i.e., one minute past the nearest previous hour. This should always be done if the observations are processed a few at a time sequentially.

#### LIST THE STATE VECTOR "ABIRD.END"

The updated state vector and covariance matrix may be listed on the line printer by typing "Y". In either case the results are inserted into the file "ABIRD.END" or any name of the user's choosing. This state vector is the same as ABIRD.STA but referenced near the end of the data span.

#### ACCEPT MORE DATA POINTS?

If more data points are to be processed type "Y". To terminate the program enter "N".

#### LIST OBSERVATIONS AND RESIDUALS?

All observations and residuals may be listed on the teletype by entering "Y" to this query.

#### EDIT RANGE DATA FILE XXXXXX.EXT

The entire range data file may be edited at this point and a new file absent of the bad data points will be created.

#### ENTER NAME OF EDITED RANGE DATA FILE

The ten character name in the form XXXXXX.EXT will be entered at this point.

#### PROGRAM BATCH

This is a simplified version of the orbit determination program. After the user answers several initial queries the program runs to completion with no additional interaction with the user. This program may be initiated by entering "RUN BATCH" on the terminal.

#### ENTER NAME OF THE FILE CONTINING THE RANGE MAGNITUDE DATA

Enter the 10 character file designation of the range magnitude data, i.e., "ABIRD.RNG".

#### ENTER NAME OF THE FILE CONTAINING THE INPUT STATE VECTOR

This file will be the a-priori orbital state vector as required by the orbit determination program. The ASCII file referred to here may be generated using the program LOAD, GENER, DIFFCR, or BATCH.

### ENTER NAME OF THE FILE CONTAINING THE UPDATED OUTPUT STATE VECTOR REFERENCED NEAR THE END OF THE DATA SPAN

Enter any name, i.e., "ABIRD.END". The state vector will be referenced to a time near the end of the data span. This also may be used as the input file to the ephemeris generation program or the orbit determination program in its sequential mode should a new batch of range data be processed.

#### ENTER STARTING OBSERVATION NUMBER

#### ENTER STOPPING OBSERVATION NUMBER

The program will run to completion after entering the above query.

Table (7). Sample output of the orbit determination program.

#### Orbital Ranging Data and Solutions

In this section the ranging data and respective solutions for the early portion of the mission will be presented. Listed immediately below are the pre-launch nominal, Standard Orbital Parameter Message (SOPM), and the best solution obtained by using the ranging data. For comparison, all three state vectors have been referenced at the same epoch. Note the close agreement between the pre-launch nominal and the final solution.

#### SUBROUTINE DESCRIPTIONS

#### PROGRAM LOAD

This program allows a user to input a state vector to disk storage in the proper format to be later read as input to ENTER, GENER, and DIFFCR. See Sect. (V).

#### PROGRAM ENTER

The range data may be entered into disk storage in its proper formant by this program. The range observations are later used as input to DIFFCR. See Sect. ( $\forall I$ ).

#### PROGRAM GENER

Ephemeris generation, state vector updates, rise and set times, and eclipse times are determined by this program. See Sect. (VII).

#### PROGRAM DIFFCR

The orbit determination program is located here. See Sect. (VIII).

## SUBROUTINE AZEL (R, T, AZ, ELV, IND, KEY)

The azimuth AZ and elevation ELV of a satellite with position R at time T is computed. Key is l for ELV greater than zero and KEY is zero for ELV less than zero. The station key is IND. Blossom Pt: IND = 1, ARCETRI, ITALY: IND = 2, AMEDABAD, INDIA: IND = 3.

## SUBROUTINE PAPER (X, T)

The state vector X at time T is listed on the line printer. Both Keplerian and Cartesian version is listed.

## SUBROUTINE BIGLET (XMB, XML)

The 7 x 7 covariance XMB is reduced in size to XML whose size is equal to the number of parameters free in the differential corrections process. XML is generally a 6 x 6 square array since the bias parameter is usually held fixed in the orbit determination process. The state error covariance matrix is with respect to the coordinate set  $(n, \xi, \eta, i, \Omega, U, BIAS)$ .

## SUBROUTINE LITBIG (XML, XMB)

The covariance XML is increased in size to XMB (7 x 7).

#### SUBROUTINE INOD (X, T, IDEN, NOBS, RMS, BIAS, LUIN, WM, LF, LR)

INOD represents an input subroutine to the orbit determination program. The state vector  $\vec{X}$  is read from the disk file into core storage.

## SUBROUTINE OUTOD (X, T, IDEN, NOBS, RMS, BIAS, LUOUT, WM, KSTART, KSTOP, NPRINT, LF, LR)

Similar to INOD except the data is read from core storage out to the disk for permanent storage.

#### SUBROUTINE RTTIME (TA, TB)

From the time TA, the time one minute from the nearest hour is computed. This time is denoted as TB. For the SOLRAD Project all epochs are referenced one minute past the nearest hour to the beginning or end of the data span. This is for convience only and thus not required for any phase of the project.

#### SUBROUTINE FANDG (X, Z, T, TN)

The state vector  $\vec{X}$  is propagated through time (T-TN) via the standard f and g series. The resulting state vector is stored as 2.

#### SUBROUTINE FORCE (K2, K3, K4, KDRAG, KSUN, KMOON)

This is a data initialization subroutine. K2, K3, K4, KDRAG, KSUN, KMOON are keys to include or exclude the perturbations J2, J3, J4, drag, Sun and Moon respectively. If the keys are set to one the respective perturbations are included and if set to zero they are excluded.

#### SUBROUTINE DEGRAD (A, B)

The Keplerian state vector A (a, e, i,  $\Omega$ ,  $\omega$ , M) is converted from degrees to radians. The result is B. The first two components remain unchanged.

#### SUBROUTINE RADDEG (A, B)

Opposite to DEGRAD. The Keplerian state vector is converted from radians to degrees. The first two components remain unchanged.

### SUBROUTINE ELRELN (ELR, ELN)

The Keplerian state vector ELR as defined above is converted to a non-singular set of elements ELN, i.e., n, e cos  $\omega$ , e sin  $\omega$ , i,  $\Omega$ , M+ $\omega$ , where n is the mean motion. Both ELR and ELN are espressed in radians.

#### SUBROUTINE ELNELR (ELN, ELR)

Opposite to ELRELN. The non-singular set of elements (for near-zero eccentricity) are converted to the Keplerian set which are expressed in radians.

### SUBROUTINE FOUR (X, TSTART, TSTOP, INT, DT)

The driving subroutine for the numerical integrator RUK.  $\vec{X}$  is the Cartesian state vector, TSTART the starting time, TSTOP the stop time, INT the print interval, and DT the step size. The print interval is thus INT·DT.

#### SUBROUTINE RUK (X)

A fourth order Runge Kutta numerical integrator.

#### SUBROUTINE DFQ (X, DX)

DFQ computes the derivatives  $\overrightarrow{\text{DX}}$  which are required by the subroutine RUK.

#### SUBROUTINE DIFFEQ (D, U, V, W, UD, VD, WD, UDD, VDD, WDD)

The accelerations due to the various perturbing forces are computed by this subroutine. D is the time; U,V,W are the inertial position components; UD, VD, WD are the inertial velocity components; and UDD, VDD, WDD are the accelerations.

## FUNCTION STPSZE (X, STEPCN)

The step size required by the numerical integrator is computed by this subroutine. STEPCN is the number of radians per step - usually set to 0.05.

#### SUBROUTINE ORBIT (ELD, X, T, TN)

The Keplerian state vector ELD is propagated analytically through the time period T-TN. Perturbations due to  $J_2$  only are included. The perturbations include only those terms not involving eccentricity. It is therefore valid only for low altitude, near circular orbits and for short time spans. ELD is expressed in degrees.

#### SUBROUTINE STATEL (X, ELD)

The Keplerian state vector ELD is computed from the Cartesian state vector  $\vec{X}$ . The units for both  $\vec{X}$  and ELD are degrees and kilometers.

#### SUBROUTINE ELSTAT (ELD, X)

The Cartesian state vector  $\vec{X}$  is computed from the Keplerian state vector ELD. The units are in kilometers and degrees.

#### FUNCTION ARKTNS (N, X, Y)

A four quadrant inverse tangent subroutine. If N = 180 a value between the range  $-180^{\circ}$  to  $+180^{\circ}$  is returned. If N = 360 the range is  $0^{\circ}$  to  $360^{\circ}$ .

#### SUBROUTINE POSION (T, X1, Y1, Z1)

The geodetic station location (X1, Y1, Z1) of Blossom Point, Maryland is computed at time T. The position is respect to inertial space. (True Eq. of Date.)

## SUBROUTINE PLACE (T, X1, Y1, Z1, XLAT, XLON)

The geocentric latitude and longitude XLAT and XLON are computed for a satellite at position S1, Y1, Z1 at time T. T is the total number of seconds measured from January 1, 0 hours 1970.

#### SUBROUTINE GHA70 (TSEC, TDAY, GHAN, DA, OMEGA)

The Greenwich hour angle GHAN is computed from the time TDAY and TSEC. TDAY represents the number of whole days from Jan. 1, 0 hours 1970. TSEC represents the number of seconds of the fractional day. For example for 0200 June 1, 1977. The modified Julian date (MJD) is 43295, TDAY = 2708, TSEC - 7200.

#### SUBROUTINE SUN (T, XS)

The position of the sun XS is given at time T. This subroutine calls the additional subroutine SUNPS (XJD, XS) for the solar position. For computational efficiency SUN merely interpolates the values obtained from SUNPS. Although SUN may be called thousands of time over an integration span, SUNPS may be called no more than several times.

#### SUBROUTINE MOON (T, XM)

The lunar positions XM is computed at time T. Moon is also an interpolation routine which calls an additional routine MOONPS.

#### FUNCTION FASTRG (ELN, T, TN)

The range of the satellite from Blossom Point is computed at time T. The satellite state vector is ELN at epoch time TN. The state vector is propagated analytically including no perturbations. This routine is used to compute the tracking covariance matrix ( $H^{T}$   $R^{-1}$  H)<sup>-1</sup>

where H is the sensitivity matrix and R is the observational variance matrix. ELN represents the state vector by the non-singular set of elements (n,  $\xi$ , n, i,  $\Omega$ , U). For computational speed the routine is written in single precision. The units for ELN are kilometers and degrees.

#### SUBROUTINE FLSTAT (ELR, X)

Similar to ELSTAT but the computations are performed in single precision. ELR represents the Keplerian state vector in radians.

#### SUBROUTINE DERIV (ELN, TIME, TN, H, NR, NC)

The sensitivity matrix H is computed for each of the times given in the array TIME. H is a NR  $\times$  NC array, where NR is the number of data points and NC is the number of state variables to be determined in the solution. NC can be from one to seven (usually six).  $H_{ij}$  is the sensitivity of the  $i^{th}$  range value with respect to a change in the  $j^{th}$  component of the state vector. ELN is the state vector with epoch TN.

#### SUBROUTINE REDUCE (KA, KB, KC, KD, KE, KF, KG, NC, NUMBER)

The number of free parameters, NUMBER, represented by the number of non-zero numbers in the calling sequence KA, KB, ... KG is determined.

#### SUBROUTINE ERASE (DX, DE, NC)

The full 7  $\times$  1 array DE is determined from DX the correction in the state vector due to the observations. DE represents the full correction. The components of DE which were held fixed in the differential corrections process are set to zero.

#### SUBROUTINE ORDER (Y, TIME, KMAX, TMAX)

The set of observations Y are ordered in ascending order with respect to TIME. The length of TIME and Y is given by KMAX. The time of the latest observation is given by TMAX.

## SUBROUTINE OUT (A, NR, NC)

The array A is listed on the line printer. The number of rows is NR and the number of columns is given by NC.

## SUBROUTINE TRAFER (A, B, NR, NC)

The array A is copied into B. The dimensions of both are  $NR \times NC$ .

#### SUBROUTINE TRNPSE (A, B, NR, NC)

The transpose of A is computed and stored in B. The dimensions of A are NR  $\times$  NC. The dimensions of B are NC  $\times$  NR.

#### SUBROUTINE ADD (A, B, C, NR, NC)

The sum of A and B is stored into C; i.e., C = A + B. The dimensions of A, B, and C are  $NR \times NC$ .

#### SUBROUTINE SUB (A, B, C, NR, NC)

The difference of A and B is stored into C; i.e., C = A - B.

#### SUBROUTINE MULT (A, B, C, NR, NS, NC)

The matrix product of A and B is computed and stored into C. The dimensions of A are NR x NS. The dimensions of B are NS x NC and the dimensions of the result are NR x NC. In other words C = AB.

#### SUBROUTINE IVERSE (BSAVE, B, NX)

This is a matrix inversion subroutine. The inverse of BSAVE is computed and stored into B. The dimensions of each are NX x NX. To reduce the possibility of underflow and/or overflow on the PDP-10 the matrix is scaled before the inverse is carried out.

### SUBROUTINE SHADOW (T, X)

The times for passage into and out of the lunar and earth penumbra and umbra are computed. This subroutine makes use of the functions DARSIN, ADOT, DOT, and FNORM. The subroutines ITRATE, FG, and SHAD are also used.
